Abstract

The use of the concept of stimuli in psychoneuroimmunological study deserves further discussion. There has, however, been a peer group of scholars that has coined a suggestion that only the terms psychological and psychosocial stressor that can be employed in psychoneuroimmunological study. This is because the definition of psychological stressor itself has not yet been determined, and even it does not exist yet in international publications. However, if we refer to the concept of stimuli-response relationships, it is the stressor, in this sense, that is essentially a stimulus that may cause stress.
